

Exception Handling Intro

30 January 2025 22:30

There are 2 stages where error can occur in a program

- During compilation -> Syntax Error ✓
- During execution -> Exceptions ✓

Syntax error & exceptions

30 January 2025 23:29

Syntax error:

--> The code written doesn't follow programming syntax/grammar. ✓

--> This Error is raised by the interpreter/compiler

--> This can be solved by correcting the syntax or grammar

Examples of syntax error

--> Forgetting symbols like colon, brackets

--> Misspelling keywords

--> Incorrect indentation

--> IndexError:

The IndexError is thrown when trying to access an item at an invalid index. →

--> ModuleNotFoundError

The ModuleNotFoundError is thrown when a module could not be found.

--> KeyError

The KeyError is thrown when a key is not found in dictionary

--> ValueError

The ValueError is thrown when a function's argument is of an inappropriate data type.

--> NameError

The NameError is thrown when accessing an object/variable that is not defined/initialized.

--> AttributeError

It is raised when calling inappropriate method

-4 -3 -2 -1
L = [1, 2, 3, 4]
0 1 2 3
L[100]

Exceptions:

If any error occurs during the execution of the program called exceptions.

- Exceptions are raised in runtime

- We can handle by writing right logic or through try except block

Note: Both syntax errors and exceptions can be handled via try except block

Correct Syntax
↓
try except

right logic
↓
try except

Why it is important to handle? ✓

--> User experience

--> security reasons

(Enhancing)
(Hacker can't hack it)

try except block

30 January 2025 23:31

1. Understanding try except block
2. Catching specific exceptions
3. Usage of else with try except
4. Finally with try except else
5. raise keyword

Understanding try except block

try:
→ { --- } Error prone code
→ { --- }
except Exception as c:
print(c)

Catching specific exceptions

try:
→ a=5
→ f=open("sample.txt", "r")
→ print(f.read())
→ { z=12/0 }
→ { print(z) }
→ { print(a) }
except Exception as c:
print(c)

✓
✓ x (Unsupported Operation)
x (ZeroDivisionError) ✓
✓
x (NameError) ✓

Note:- Remember atleast 10 Errors:

- go with specific Exception which can handle those errors
- At the end u keep one General Exception

try:-

```

except Err1
except Err2
:
except Exception as e:
    print(e)

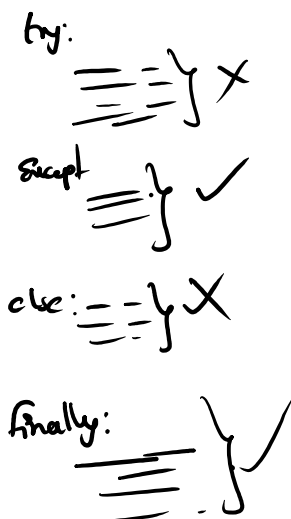

```

Usage of else with try except

Note:- put your Error-free code inside else block, which you think should get executed after successful code execution in try block.

Finally with try except else

Scenario:-

Scenario:-

try:

```

conn = cursor ( user, pass, ip, port ) ✓
prod-table = open
prod-table = conn.connect ("products") ✓
(prod-table). insert (" ", " ", " ", " ") ✓
(prod-table). save() ✓

```

except:

print(e) ✗

else:

prod-table.export (id=1)) } ✗

finally:

conn.close() ✓

Bluetooth ✓

File =

Ex:- DB connections, file access, cloud services etc.

raise keyword

→ It will allow the developer to raise specific exceptions with execution of code

Ex:-

def withdraw (amount, balance = 10000):

if amount > balance: ✗
raise Exception ("your balance is low")

elif amount < 0: ✓
raise Exception ("your amount should be positive")

else: ✓
amount-withdrawn = balance - amount
return amount-withdrawn

10 points
10

definition

try:

a = withdraw (-100) ✓

except Exception as e:

print(e) # "your amount should be positive"

```
except Exception as e:  
    print(e) # "you must read be pinkie"  
else:  
    print(a)
```
